Crop Update March 22, 2018

Building Strong and Vibrant New York Communities

Diversity and Inclusion are a part of Cornell University’s heritage. We are a recognized employer and educator valuing AA/EEO, Protected Veterans, and Individuals with Disabilities.
 Dates of interest:

**Wednesday, March 28, 2018**-Core Pesticide Training and License test- see info in Crop Update  
Location: CLEREL

**May 2, 2018**- Coffee Pot Season Begins!  
10:00am- Clover Hill Farm, 10401 Side Hill Rd., North East, PA 16428  
See full coffee pot schedule in this edition, and on [https://lergp.cce.cornell.edu/](https://lergp.cce.cornell.edu/)
Economics of pH

Research once indicated that Concors were able to tolerate low pH. That was actually true. At the time the economic and viticulture reality was an entirely different world. Balanced pruned umbrella kniffin training systems were the best known way to manage juice grapes at the time. Advanced fungicide, canopy design improvements and machine harvesting all developed while agricultural commodity prices would trend lower for the next fifty years.

Our new economic reality is to maximize yields. Our commercial vineyards are now typically in a constant state of over-cropped, unless frost events allow vines to rest. This model, while not sustainable, also completely eliminates the ability of the vine to “tolerate” low pH. In our new economic reality vines demand higher pH.

While some vineyards have a pH over 6.0, most growers need to invest $200 per acre over the next 3 years. While some soils change easier than others, chart 1 shows what a typical grower with a soil pH of 4.9 would likely need to budget for the next decade. Chart 1 shows both the cost per year and the total accumulating cost over time.

After about three years the grower will start to see benefits. It is more than likely that a balanced yield will be 1-2 tons higher as vine size increases. If that’s not the case, savings would be realized as nutrients like potassium become more available. It is possible that savings in potash would exceed $350 per acre. At a minimum, the increase in potash availability would save a grower $125 per acre over years 3-10.

It’s also important to keep in mind, these savings are calculated under the assumption that the desire is to maintain vine size and soil health. It is often possible to neglect potassium application for 5 years or more. Vine size will eventually decline, yield will decline, and brix will also decline. Eventually you might not even need to prune! Finally, the vineyard could be abandoned or the grower could adopt a soil remediation strategy to replenish organic matter, potassium and perhaps phosphorus levels to allow vines to recover. This remediation is intensive, expensive and must be completed without the support of vineyard production (yields will return after). Additional nutrient applications will be necessary as availability will be low, because part of a remediation strategy would be a 5-10 plan to increase soil pH.
INTRODUCTION
In the last crop update, we discussed soil pH and its relationship to nutrient availability in vineyards. Maintaining appropriate soil pH (5.5 – 6) in most Lake Erie soils is an uphill battle, due to the interaction of many sources of soil acidification. In this article, we are going to explore how to increase soil pH with lime.

Commercial agricultural lime is made from finely ground limestone or chalk. It may contain calcium and/or magnesium carbonates, oxides or hydroxides. The various compositions of liming materials offer different benefits, but all work in primarily the same way.

HOW AGRICULTURAL LIME WORKS
When lime is introduced into the soil solution, it reacts with H2O and releases hydroxide anions (OH⁻) and/or bicarbonates (HCO₃⁻) depending on the composition of the lime. These anions bind to positively charged hydrogen ions in the soil solution, neutralizing them. Remember that acidic soils (low pH) have a higher concentration of H⁺ ions.

As lime reacts in the soil solution and raises the pH, Al₃⁺ and Fe₃⁺ precipitate as Al(OH)₃ and Fe(OH)₃, and allow Ca²⁺ and/or Mg²⁺ to replace them on cation exchange sites. These reactions are extremely important to vine nutrition, as calcium and magnesium are made available and toxic aluminum is given a one-way ticket out of the rooting zone. It is important to consider, however, that Ca²⁺ and/or Mg²⁺ may outcompete K⁺ for cation exchange sites (K has a weaker charge), so it is important to monitor potassium levels and supplement as needed.

LIME SPECIFICATIONS
Liming materials differ in their neutralizing value and their degree of fineness, which influence their effectiveness in bringing up soil pH. The neutralizing value of a liming material, referred to as its purity, is measured as percent calcium carbonate equivalence (CCE, Table 1). The higher the CCE, the more acid that a unit weight of a given liming material will neutralize.

Table 1 Calcium Carbonate Equivalent of Some Liming Materials, adapted from Havlin et al. 1999

<table>
<thead>

<tr>
<td>Slag, CaSiO₃</td>
<td>86</td>
</tr>
</tbody>
</table>

Finness of a liming material also factors into its effectiveness. The surface area in contact with the soil influences the rate of the chemical reactions that neutralize the soil. The finer the particles, the faster they neutralize the soil acid. Fineness is expressed as the percentage of particles that will pass through a 100-mesh sieve. Calcium oxide and calcium hydroxide are powders with maximum fineness (100%) about the consistency of flour, while limestones must be crushed to decrease particle size. Crushed limestone may have a range of particle sizes and coarser particles will take longer to react with the soil solution. As a general rule, for dolomite and calcite to have the same effectiveness in raising pH at the same application rate, dolomite must be given twice as long to react or be ground twice as fine (Havlin et al. 1999).

Lime addition recommendations are typically made based on 80% CCE and 60% fineness (Table 2). Depending on the specifications of the liming material chosen, the recommended liming rate may need to be adjusted up or down. The supplier of the lime you are using should provide you with the specifications you need to make an educated decision on the application rate needed to achieve the desired pH increase.

APPLYING LIME

In no till systems, applying lime does not provide instant gratification. Several studies reported that 10 to 14 years were required for surface applied lime to raise soil pH at a depth 15cm (6in) without incorporation (Havlin et al. 1998). Many variables exist that contribute to how quickly a desired pH may be achieved in vineyard soils. Initial pH, organic matter content, texture, moisture, cation exchange capacity, and compaction of a soil can all influence how effective broadcasting lime may be in increasing soil pH and the time required to reach the desired pH. The presence of cover crops, weeds, and the specifications of the lime used also play a role.

Soil texture, water holding capacity and compaction vary across vineyards as well, which means that the soil pH (which varies spatially as well) may not respond uniformly to lime application at the same rate. Some growers in the region are using variable rate lime application to make sure lime additions are well matched to the soil conditions in the targeted area.

Broadcasting dry lime (Figure 1) either after harvest or before budbreak is the most typical practice in vineyards, though more expensive fluid lime may offer an increased reaction rate and other advantages. For lime additions exceeding 2 tons per acre, it is advisable to split the addition over successive seasons.

SUMMARY - GENERAL LIMING GUIDELINES

- Take representative soil samples at least every 3 years to determine lime requirements and evaluate effects.
- Check the specs! Lime with high CCE has higher neutralizing capacity. Finer lime particles react quickly and are mobile in the soil.
- Surface pH may not tell the whole story but keeping it above 6.0 constantly will help increase subsoil pH over time.
- Liming materials add Ca and/or Mg to the soil, so watch those K levels and add potash if necessary.

REFERENCES

“CORE” Pesticide Training and Pesticide Applicators License Exam  
March 28, 2018  
Cornell Lake Erie Research and Extension Laboratory (CLEREL)  
6592 West Main Road  
Portland, NY 14769

Space is limited ---Pre-registration is required for both sessions

CORE TRAINING  
WHEN:       Wednesday, March 28, 2018 from 9 AM to 12:15 PM  
WHERE:      CLEREL Meeting room  
COST:       $15  
3.0 Pesticide recertification credits in the CORE category have been applied for.

The CORE training session is also designed as a review prior to taking the Commercial or Private Pesticide Applicator exam but is not required prior to taking the exam.

Preregistration for the training using the enclosed course registration form is required by March 26, 2017.  
Or sign up on-line at https://lergp.cce.cornell.edu

Questions on the training session should be directed to Kate at (716) 792-2800 ext 201

PRIVATE AND COMMERCIAL NYS PESTICIDE EXAMINATIONS  
WHEN:       1 PM  
WHERE:      CLEREL Meeting room  
COST:       $100  
REGISTRATION:  NYS Department of Environmental Conservation (DEC) requires you to register for entrance to the exam session with the Buffalo DEC office at (716) 851-7220.

DEADLINE for registration to take the test is March 9, 2018.  To register, call the DEC at (716) 851-7220.  You will then be sent an exam application form and test instructions by the DEC.

Any questions about your eligibility to take an exam or the status of your current certification should be directed to the Buffalo DEC office at (716) 851-7220.

Commercial Applicators:  You will need the “Core Manual” and the category manual for the area(s) in which you will be certifying.

Private Applicators:  You will need to get the “Core Manual” plus the private category manual for the area in which you will be certifying.

CORE and category training manuals are available through the Cornell Store by calling (800) 624-4080 or the web-site link: http://store.cornell.edu/c-876-manuals.aspx

Questions on Pesticide Examinations should be directed to the NYS DEC at (716) 851-7220.
2018 CORE PESTICIDE TRAINING
REGISTRATION FORM
Wednesday March 28, 2018

Space is limited – pre-registration is required.

To register for the training, fill out and return registration form to:

ATTN: Kate
Lake Erie Regional Grape Program
CLEREL
6592 West Main Road
Portland, NY 14769

Name(s) __________________________________________
________________________________________
________________________________________

Address __________________________________________

INSURING GRAPES
NY, 2017

Crop insurance is a safety net for farmers that helps you manage risk. If you have a crop failure, crop insurance can help you farm again next year.

Important Insurance Deadlines
- **Aug. 15, 2017:** Premium Billing Date
- **Nov. 20, 2017:** Sales Closing, Policy Change, Cancellation, Termination Date
- **Nov. 20, 2017:** End of Insurance Period
- **Jan. 15, 2018:** Acreage / Production Report Date

Over 40 grape varieties are insurable in these counties:
- Cattaraugus
- Chautauqua
- Erie
- Niagara
- Ontario
- Schuyler
- Seneca
- Steuben
- Suffolk
- Ulster
- Wayne
- Yates

Grapes in other counties may be insured by written agreement from RMA

NYS Grape Crop Insurance Performance

For every $1 grape producers spent on crop insurance premiums from 2012 to 2016, they received $2.07 in losses paid, on average
